ABSTRACT

One embodiment of an optical system described herein comprises a source including light emitting diode chip and a homogenizer. One embodiment of the homogenizer comprises an entrance face positioned to receive light from the source, the entrance face having a first shape, a body configured to homogenize the received light and an exit face, the exit face parallel to the primary emitting face of the source. The homogenizer can emit light with a half angle that is at least 80% of the half angle of light entering the homogenizer.

LED HOMOGENIZER**RELATED APPLICATIONS**

This application is a continuation of, and claims a benefit of priority under 35 U.S.C. §120 of the filing date of U.S. patent application Ser. No. 13/243,857, entitled "LED Homogenizer" by Duong et al., filed Sep. 23, 2011, which claims the benefit of priority under 35 U.S.C. §119(e) to U.S. Provisional Patent Application No. 61/386,050, entitled "High NA Refractive LED Secondary Optic," by Duong, filed Sep. 24, 2010, U.S. Provisional Patent Application No. 61/406,503, entitled "High NA Refractive LED Secondary Optic," to Duong, filed Oct. 25, 2010, and U.S. Provisional Patent Application No. 61/479,661, entitled "High NA Refractive LED Secondary Optic," to Duong et al., filed Apr. 27, 2011, and U.S. Provisional Patent Application No. 61/487,511, entitled "LED Homogenizer" by Duong, filed May 18, 2011, each of which is fully incorporated by reference herein.

TECHNICAL FIELD

Embodiments described herein are related to optics for homogenizing light within an optical signal. More particularly, embodiments described herein are related to various ways of attaining desired spatial homogenization from one or more light sources.

BACKGROUND

Light emitting diodes (LEDs) are inherently not spatially uniform. The non-uniformity may come from non-radiative metal contacts, uneven phosphor distribution, or the use of multiple LEDs emitting the same or different colors in one optical system. For broad beam angles, spatial variation at illuminated plane may be tolerated. As the beam angle is decreased, spatial non-uniformities become much more distinguishable.

In the conventional art, secondary optics may include one or multiple LEDs of the same or different colors. If the secondary optics projects the source intensity onto a surface, spatial separations of the source create spatial separation at the illuminated plane. LEDs of different colors illuminate a given plane including chromatic spatial separation. One LED with spatial non-uniformities may project spatial non-uniformities to the illuminated plane.

Homogenizers have been used in projection systems. However, the homogenizers were often remote from the light source and included lenses upstream of the homogenizer to focus light into the homogenizer. In a DLP system, the ultra-high performance (UHP) source is imaged into the entrance of the light bar.

There remains a need however to achieve uniform spatial homogenization from one or multiple LEDs for narrow beam angles.

SUMMARY

Embodiments disclosed herein demonstrate multiple ways of attaining spatial homogenization from one or more LED sources. In some embodiments, such homogenization may be achieved while maintaining system radiance. In some embodiments, tradeoffs may be made with respect to system efficacy vs. system radiance. In some embodiments, an LED homogenizer disclosed herein may be an extension of High NA secondary optics. Examples of High NA Refractive LED secondary optics are disclosed in U.S. Provisional Patent

2

Application No. 61/386,050, filed Sep. 24, 2010, No. 61/406,503, filed Oct. 25, 2010, and No. 61/479,661, filed Apr. 27, 2011, all of which are hereby incorporated by reference in their entireties. In some embodiments, an LED homogenizer disclosed herein may be coupled to non-High NA optical systems.

In designing an optical system, it may be advantageous to control the spatial homogenization of light projected towards a plane. Embodiments described herein describe an LED homogenization system to create spatial uniformity at an exit aperture. One embodiment of an optical system described herein includes a source having a primary emitting face, the source comprising at least one LED chip. The optical system also comprises a homogenizer, the homogenizer comprising an entrance face parallel to the primary emitting face of the source and positioned to receive light from the source, the entrance face having a first shape, a body configured to homogenize light by reflecting the received light a plurality of times off sidewalls of the body and an exit face configured to emit light, the exit face parallel to the primary emitting face of the source, wherein the homogenizer is configured to emit light from the exit face that has a half angle that is at least 80% of the half angle of light entering the homogenizer.

Another embodiment of an optical system described herein comprises an LED chip and a homogenizer axially aligned with a primary emitting face of the LED chip. The homogenizer comprises an entrance face positioned to receive light from the light emitting diode, the entrance face having a first shape, and a body configured to homogenize light by reflecting the received light a plurality of times off sidewalls of the body. The homogenizer further comprises an exit face configured to emit light, the exit face parallel to the primary emitting face of the LED chip. The homogenizer is configured to emit light from the exit face that has a half angle that it at least 80% of the half angle of light entering the homogenizer.

According to one embodiment, the exit face has at least a minimum area necessary to conserve radiance. For example, the exit face can have an area at least equal to

$$\frac{n^2 A \Omega}{n'^2 \Omega'}$$

wherein Ω is the effective solid angle in which light enters the homogenizer, Ω' is the effective solid angle whereby light leaves the homogenizer, A is the area of the entrance face, n is the refractive index of the medium from which light is received by the homogenizer, n' is the refractive index of material into which the homogenizer emits. In a more specific example, the exit face has an area at least equal to

$$\frac{n^2 A \pi}{n'^2 \Omega'}$$

wherein Ω' is the effective solid angle whereby light leaves the homogenizer, A is the area of the entrance face, n is the refractive index of the medium from which light is received by the homogenizer, n' is the refractive index of material into which the homogenizer emits.

According to one embodiment, the homogenizer is separated from the light source by an air gap. In another embodiment an encapsulant with a higher index of refraction than air surrounds the LED chip. The entrance face of the homogenizer contacts the encapsulant. For example, the encapsulant

can have approximately the same index of refraction as the homogenizer and/or a lens optically coupled to the homogenizer.

The homogenizer can act to shape light into a desired shape, including geometric and arbitrary shapes. For example, the entrance face of the homogenizer can have a first shape and the exit face can have a second shape different than the first shape. The homogenizer can include a set of transition features to transition from the first shape to the second shape. The body of the homogenizer may be tapered between the entrance face and exit face and can include a set of facets transitioning to the exit face having the second shape.

In addition to the LED and homogenizer, an embodiment of a light distribution system can include a series of lenses optically coupled to the exit face of the homogenizer. The lenses in the series can be configured, in combination, to successively reduce a beam angle of light from a first beam angle to an emission beam. In another embodiment, the light distribution system comprises an optical device optically coupled to the exit face of the homogenizer, the optical device configured to emit at least 70% of the light entering the optical device from the homogenizer in a controlled beam angle.

Another embodiment described herein can include a method of homogenizing light comprising i) receiving light at an entrance face of a homogenizer from an LED chip, the entrance face having a first shape and arranged parallel to the primary emitting surface of the LED chip and the homogenizer axially aligned with the LED chip; ii) homogenizing the received light within the homogenizer; and iii) emitting the homogenized light at an exit face parallel to the primary emitting surface of the LED chip. Homogenizing light can include reflecting the light a plurality of times off sidewalls of the body of the optical element. The method can further include emitting light in a second shape different than the first shape. One embodiment of the method may also include emitting the homogenized light into a series of lenses that are configured, in combination, to successively reduce a beam angle of light from a first beam angle to an emission beam angle and emit in the emission beam angle at least 70% of the light entering the series of lenses from the homogenizer. Another embodiment of the method can include emitting the homogenized light into an optical device optically coupled to the exit face of the homogenizer, the optical device configured to emit at least 70% of the light entering the optical device from the homogenizer in a controlled beam angle.

According to example embodiments, systems and methods for homogenizing light are provided for. A method for homogenizing light may include receiving light at an entrance face, the entrance face having a first shape. The received light may then be homogenized within a body of an optical element and emitted at an exit face of the body of the optical element. In the example embodiment, the exit face may have a second shape, and the first shape may have different geometric characteristics than the second shape. Additionally, the second shape has a greater surface area than the first shape. Furthermore, the entrance face may be configured to receive light from a light emitting diode, and the exit face may be coupled to at least one lens.

BRIEF DESCRIPTION OF THE FIGURES

A more complete understanding of various embodiments of optical systems and devices and the advantages thereof may be acquired by referring to the following description, taken in conjunction with the accompanying drawings in which like reference numbers indicate like features and wherein:

FIG. 1 is a diagrammatic representation of an embodiment of an optical system;

FIG. 2 provides a diagrammatic representation of one embodiment of positioning a homogenizer relative to a source;

FIG. 3 is a diagrammatic representation of another embodiment of positioning a homogenizer relative to a source;

FIG. 4 is a diagrammatic representation of yet another embodiment of an optical system;

FIG. 5 is a diagrammatic representation of yet another embodiment of an optical system;

FIG. 6 is a diagrammatic representation of yet another embodiment of an optical system;

FIG. 7 is a diagrammatic representation of one embodiment of elements within an optical device;

FIGS. 8A-D are diagrammatic representations of one embodiment of a homogenizer housing structure;

FIGS. 9A-B are diagrammatic representations of one embodiment of a homogenizer;

FIGS. 10-15 are diagrammatic representations of model illumination patterns for embodiments of an optical system;

FIG. 16 is a chart of radiant intensity versus beam angle for one embodiment of an optical system;

FIG. 17 is a diagrammatic representation illustrating the advantage of a high percentage of light in beam;

FIG. 18 is a diagrammatic representation of one embodiment of projecting light from an optical system to create a square or rectangular optical pattern;

FIG. 19 is a flow chart representing at least one embodiment for determining the shape of a homogenizer;

FIGS. 20 and 21 are diagrammatic representations of other embodiments of optical systems.

DETAILED DESCRIPTION

The disclosure and various features and advantageous details thereof are explained more fully with reference to the exemplary, and therefore non-limiting, embodiments illustrated in the accompanying drawings and detailed in the following description. Descriptions of known starting materials and processes may be omitted so as not to unnecessarily obscure the disclosure in detail. It should be understood, however, that the detailed description and the specific examples, while indicating the preferred embodiments, are given by way of illustration only and not by way of limitation. Various substitutions, modifications, additions and/or rearrangements within the spirit and/or scope of the underlying inventive concept will become apparent to those skilled in the art from this disclosure.

As used herein, the terms “comprises,” “comprising,” “includes,” “including,” “has,” “having” or any other variation thereof, are intended to cover a non-exclusive inclusion. For example, a process, product, article, or apparatus that comprises a list of elements is not necessarily limited to only those elements but may include other elements not expressly listed or inherent to such process, product, article, or apparatus. Further, unless expressly stated to the contrary, “or” refers to an inclusive “or” and not to an exclusive “or”. For example, a condition A or B is satisfied by any one of the following: A is true (or present) and B is false (or not present), A is false (or not present) and B is true (or present), and both A and B are true (or present).

Additionally, any examples or illustrations given herein are not to be regarded in any way as restrictions on, limits to, or express definitions of, any term or terms with which they are utilized. Instead these examples or illustrations are to be regarded as being described with respect to one particular

5

embodiment and as illustrative only. Those of ordinary skill in the art will appreciate that any term or terms with which these examples or illustrations are utilized encompass other embodiments as well as implementations and adaptations thereof which may or may not be given therewith or elsewhere in the specification and all such embodiments are intended to be included within the scope of that term or terms. Language designating such non-limiting examples and illustrations includes, but is not limited to: “for example,” “for instance,” “e.g.,” “in one embodiment,” and the like. Furthermore, any dimensions, materials or other such characteristics are provided by way of example and not limitation.

FIG. 1 is a diagrammatic representation of an embodiment of an optical system including light source **105** and a homogenizer **120**. In one embodiment, light source **105** can include an LED chip or an array of LED chips (including for example an array of LEDs emitting different colors of light (e.g., an RGB LED array)), an LED(s) used in combination with phosphors or other light sources including sources that act as ergodic system.

In general, the purpose of a homogenizer is to allow light to bounce multiple times of sidewalls as the light propagates along the homogenizer, causing spatial variation in the source to be reduced. Accordingly, the flux per unit area exiting the homogenizer is preferably or substantially uniform. By way of example, but not limitation, homogenizer **120** can homogenize light so that the peak to valley variation in flux per unit area is less than 10% or other percentage (e.g., 5%).

In the embodiment of FIG. 1, the optical axis of homogenizer **120** is aligned with the center of source **105** and includes an entrance face **122** and an exit face **124**. In other embodiments, the optical axis may be off center. Entrance face **122** can be the same size as or larger than and be parallel with the primary emitting face of light source **105**. According to one embodiment, the exit face **124** (physical or virtual) of the homogenizer **120** may be parallel to the primary emitting plane of light source **105** (e.g., parallel to the primary exit face of an LED), so that homogenized light is emitted in a plane parallel to the emitting plane of light source **105**. Homogenizer **120** can have a variety of shapes such as tapered or untapered. Moreover, the entrance face **122** of homogenizer **120** can have a different shape than the exit face **124**. In other example embodiments, the exit face **124** of the homogenizer may not be parallel to the primary emitting plane of the light source **105**.

The entrance face of homogenizer **120** defines the entrance aperture. For a given entrance face **122** size, the size of exit face **124** of the homogenizer **120** can be determined from the following EQNS. 1-4 in order to conserve brightness.

$$\frac{\phi}{n^2 A \Omega} = \frac{\phi'}{n'^2 A' \Omega'} \quad [\text{EQN. 1}]$$

$$A' = \frac{n^2 A \Omega}{n'^2 \Omega'} \quad [\text{EQN. 2}]$$

wherein Ω is the effective solid angle in which light enters the homogenizer, Ω' is the effective solid angle whereby light leaves the homogenizer, A is the area of the entrance face, n is the refractive index of the medium from which light is received by the homogenizer, n' is the refractive index of material into which the homogenizer emits.

Since the intensity distribution out of the exit face **124** may be air, the n' value is approximately 1. Furthermore, if there is a gap between light source **105** and homogenizer **120**, n is also

6

approximately 1. Since LEDs are extended sources, the value for Ω is π . With these conditions, the brightness equation reduces to:

$$A' = \frac{n^2 A \Omega}{n'^2 \Omega'} \quad [\text{EQN. 3}]$$

$$A' = \frac{A \pi}{\Omega'} \quad [\text{EQN. 4}]$$

In general, the homogenizer **120** can be configured not to change the angular distribution of light. Therefore, the area of exit face **124** can be approximately the same (or larger) than the entrance face of homogenizer **120** to conserve brightness. A larger exit face (given the similar indices of refraction of the media at either end of the homogenizer) will lead to a reduction in beam angle, but preferably, the size of exit face **124** is selected so that the difference in beam angle between the light emitted from exit face **124** and received at entrance face **122** such that the half angle of light emitted from the homogenizer **120** at a physical or virtual face is 80% of up to equal to the half angle of the light entering the homogenizer **120**. Methods for determining the solid angle for a square or rectangular beam are described in U.S. patent application Ser. No. 12/788,094, which is hereby fully incorporated by reference herein.

The above example assumes a source emission angle of pi steradians (solid angle), but in cases where the source emission angle is different, the equation still applies. For instance, if the source only emits into a 60 deg full cone, then A' is equal to $A \text{Pi}(\gamma/3/\Omega')$.

FIGS. 2 and 3 are diagrammatic representations of embodiments of positioning homogenizer **120** relative to source **105**. In the embodiments of FIGS. 2 and 3, source **105** comprises LED chip or die **200** surrounded by phosphor particles **201** distributed in encapsulate **203** and disposed in a cavity **202**. In the embodiments of FIGS. 2 and 3, source **105** has a generally flat emitting surface **209**, in this case, parallel to the primary emitting face **207** of LED **200**. In other embodiments, source **105** could have other configurations. In one embodiment, the entrance face **122** of homogenizer **120** can be the same size as or larger than the emitting surface **209** of source **105**. That is, the entrance face **122** of homogenizer **120** can encompass the source. The cavity can be defined by or lined with a reflective material, such as TiO_2 and can have a variety of shapes.

The phosphor particles **201** can be disposed in the encapsulant **203**, coated on top of the encapsulant, coated on the LED or otherwise disposed between LED **200** and the entrance face of homogenizer **120**. The entrance aperture **117** of homogenizer **120** of multi-element optical stack **110** is defined by exit aperture of the source, in this example, the cavity exit.

One difference between FIGS. 2 and 3 is that, in FIG. 2, the homogenizer **120** is separated from the emitting surface of source **105** by an air gap **212**, whereas, in FIG. 3, the homogenizer **120** directly contacts the emitting surface of the source (i.e., the surface of the encapsulant). For purposes of the following discussion, the embodiment of FIG. 2 will be referred to as “non-coupled,” while the embodiment of FIG. 3 will be referred to as “coupled.” The use of the phrase “non-coupled,” in this context, merely means that a gap exists between the exit aperture of source **105** and entrance face of homogenizer **120**, though the source and homogenizer are still operatively coupled.

In general, the size of the gap in the non-coupled solution can be selected so that the numerical aperture (NA) of a

system incorporating homogenizer **120** remains high. By way of example, but not limitation, the gap is preferably less than 500 microns and can be approximately 100-200 microns.

While the non-coupled solution offers the advantage of a smaller exit aperture size to conserve brightness, the non-coupled solution may experience some losses. FIG. 2 illustrates several possible light paths that result in losses. At the phosphor to air interface, two events are possible. The ray refracts into air, with corresponding Fresnel reflection, or the light is reflected back into the encapsulant due to total internal reflection ("TIR"). Because phosphor is an ergodic system, rays that are reflected will have a probability of being scattered into a non-trapping mode. This continues until the light eventually escapes into the air interface between the phosphor and the homogenizer or is absorbed by the LED chip, the cavity walls, etc. Fresnel reflections at the phosphor to air interface will experience the same dynamics as the totally internally reflected light. At the air to the homogenizer interface, the light may refract into the homogenizer. Fresnel reflections off this interface will experience the same dynamics as the totally internally reflected light. Therefore, according to one embodiment, the cavity walls, chips and everything within the cavity should be as non-absorptive as possible.

In the coupled solution, light will typically not experience TIR at the phosphor/homogenizer interface as the materials of homogenizer **120** and encapsulant **203** can be selected to prevent or reduce this phenomenon as well as Fresnel reflection. Thus, while the coupled solution may require a larger exit face (or system exit aperture), the coupled solution can be overall more efficient. It is estimated that the difference in total emitted flux between coupling and not coupling may be small (5-30%). The loss is dependent on the type of chip or the geometry of the source, among other things. Thus, the selection of a coupled or non-coupled system can depend on the tradeoffs between exit aperture size and losses in total emitted flux.

Returning to FIG. 1, the length of the homogenizer **120** may further alter or modify the light distribution at the exit face **124** of the homogenizer **120**. More specifically, when increasing the length of the homogenizer the light within the homogenizer **120** may be more uniformly homogenized if the sidewalls of the homogenizer **120** are not tapered. Tapered homogenizers will require a longer length for the same level of homogenization than untapered homogenizers. Accordingly, the longer the length of the homogenizer, the more homogenized the light exiting the homogenizer **120**.

The material for the homogenizer **120** may be any substance or material that minimally absorbs the emitted light from the light source **105** in the emitted spectrum. Also, because the material of the homogenizer **120** may be in closer proximity to phosphor particles, a PMMA or silicone based material may form the homogenizer **120**.

The shape of homogenizer **120** can be selected so that homogenizer **120** does not alter the angular distribution of the light, just the spatial distribution. According to one embodiment, the shape of the homogenizer **120** can be selected so that the half angle of light emitted from the homogenizer at the physical or virtual exit face is from 80% to equal to the half angle of light entering homogenizer **120**. Furthermore, while the exit face **124** can be any desired size, preferably the exit face **124** of the homogenizer **120** is greater than 95% of the size of the entrance face, and in one embodiment is between 95-105% of the size which is necessary to conserve radiance.

Homogenizer **120** may be used in conjunction with a variety of optical elements including imaging lenses. According to one embodiment, homogenizer **120** can be used with a

multi-element optical stack. FIG. 4 is a diagrammatic representation of one embodiment of an optical system including light source **105** and a multi-element optical stack **110** having first lens **112** and a second lens **114** used in combination with homogenizer **120**. Multi-element optical stack **110** can be an imaging optical stack or a non-imaging optical stack and include a series of optical elements (lenses or portions of lenses arranged as doublets, triplets or other lens structures). According to the embodiment of FIG. 4, homogenizer **120** is a rectangular homogenizer with an exit face **124** at the plano surface of first lens **112**. Homogenizer **120**, according to one embodiment, is arranged to have a high NA. In order for brightness to be conserved (or be within some percentage of being conserved) an appropriate amount of light must be relayed from each lens to the next, such as when relaying light from first lens **112** to second lens **114**, the projected beam angle of each lens can be within the acceptance cone of the next more distal lens. According to one embodiment, the projected beam angle of a lens is smaller than the projected beam angle of light emitted by the next more proximal lens. Thus, for example, in FIG. 4, the projected beam angle of second lens **114** can be less than that of first lens **112**.

According to one embodiment, the multi-element optical stack can include a series of lenses that work in combination to relay approximately 100% or other percentage of light entering first lens **112** to far field. In some embodiments approximately 100%, or other high percentage (e.g., greater than 70%, 75%, 80%, 85%, 90% or 95%) of the light entering lens **112** is relayed.

Furthermore, the lenses of multi-element optical stack **110** can work in combination to achieve a high percentage of light in beam. That is, for a given projected beam angle, a high percentage of the light emitted from second lens **114** is in that beam angle (e.g., greater than 70%, 75%, 80%, 85%, 90%, 95% or 98% of light in beam). More so, in other example embodiments the projected beam angle may include any desired or required percentage of the light emitted from the second lens. The various lenses can be selected, in one embodiment, to reduce the beam angle to 1.0-25 degree half angle.

FIG. 5 is a diagrammatic representation of another embodiment of an optical system comprising light source **105**, homogenizer **120** and an optical device **121**. Separate optical device **121** can be a device such as described in U.S. Pat. No. 7,772,604, which hereby fully incorporated by reference, that conserves radiance, or a selected percentage of radiance, while controlling beam angle to provide a desired light distribution in the beam angle. Optical device **121** and homogenizer **120** may be separate pieces or may be integrated.

Optical device **121** can have an exit face **129** of any desired size. Preferably, though, the exit face **129** is at least a minimum size necessary to conserve radiance or is greater than 95% of the size necessary to conserve radiance for a desired emission half angle. Optical device **121** can be shaped so that approximately 100%, or other high percentage (e.g., 70%, 75%, 80%, 85%, 90% or 95%) of the light entering optical device is relayed to far field. Furthermore, for a given projected beam angle, a high percentage of the light emitted from optical device **121** is in that beam angle (e.g., greater than 70%, 75%, 80%, 85%, 90%, 95% or 98% of light in beam).

Optical device **121** can be configured with shaped sidewalls to reduce light distribution received from real or virtual exit face **124** into the selected beam angle through TIR in a single optical element. By way of example, but not limitation, optical device **121** can reduce the beam half angle to 10-60 degrees.

FIG. 6 is a diagrammatic representation of another embodiment of an optical system 100 having a light source 105 and a multi-element optical stack 110 and a homogenizer 120. According to one embodiment, multi-element optical stack 110 includes a first optical element 125, a second optical element 127 and a third optical element (represented as second lens 114). First lens 112, in this embodiment, is a doublet formed from optical element 125 and optical element 127. Optical element 125 and homogenizer 120 are integrated in a homogenizer housing structure 150 that includes optical element 125 portion and a homogenizer 120 portion. Optical elements 125 and 127 are coupled together (e.g., using optical adhesive or other joining mechanism).

According to one embodiment, multi-element optical stack 110 can be formed so that exit aperture 118 of the optical stack 110 or the exit face 124 of the homogenizer 120 is (within manufacturing tolerances) or is at least the size necessary to conserve radiance for a given system in a particular medium (e.g., air or another medium).

In another embodiment, the exit aperture 118 of the optical stack 110 or exit face 124 of homogenizer 120 can be between 95-105% of the size necessary to conserve radiance. In other embodiments, the exit aperture of the optical stack 110 or exit face of homogenizer 124 can be at least some percentage (i.e. 70%, 75%, 80%, 85%, 90% or 95%) of the size necessary to conserve radiance.

Having a smaller exit aperture of the optical stack 110 reduces brightness. However, this may result in a desired intensity distribution yielding softer illumination edges. Thus, the selection of exit aperture can be made to balance size, profile and brightness.

In the embodiment illustrated in FIG. 6, optical element 125 comprises a first surface 151 facing light source 105 and a second surface 152 on the opposite side of lens 112 (an "exit surface" 152). Surface 151 can be flat or have some other desired shape. Exit surface 152 of optical element 125 is concave and complements convex entrance surface 154 of optical element 127. The surface of optical element 127 on the opposite side of optical element 127 from the source (i.e. exit surface 156 is also convex. The surface of lens 114 facing the source (i.e. entrance surface 158) is slightly concave, while the surface of lens 114 facing away from the source (i.e. exit surface 160) is convex.

The surfaces of the optical elements/lenses may be coated, textured or patterned to achieve desired results. For example, homogenizer entrance face 122, exit surface 156, second lens entrance surface 158 and/or second lens exit surface 160 can be coated with an AR coating or patterned with an AR pattern, such as moth eye. In one embodiment, surface 160 can be textured to provide more diffuse light. As another example, surfaces 156 and 160 can be patterned with diffractive optical elements. Diffractive optical elements (DOEs) are optical components that spatially vary a lens thickness to change the optical path length that the wavefront experiences at various points along a lens. DOEs are typically patterned microstructures on the surface of a lens. In one embodiment, a DOE is selected to control color, such as for reducing blue-red separation or chromatic aberration.

Further, homogenizer 120 extends from surface 151 to entrance face 122, preferably parallel to and coaxially with the optical axis of lens 112. Homogenizer 120 can be straight or tapered and may be configured to shape light into a square, rectangle, circle or other shape (including arbitrary images and letters). Furthermore, while homogenizer 120 is depicted with a straight optical axis, homogenizer 120 may curve or change directions such that the exit face 124 is not parallel to or aligned with the emitting surface of the source.

FIG. 7 is diagrammatic representations of one embodiment of an optical device 161 comprising an LED housing 162, homogenizer housing structure 150, a lens housing 164 and second lens portion 155. Optical device 161 incorporates an embodiment of the optical system of FIG. 6, with homogenizer housing structure 150 having a homogenizer 120 portion and a first optical element 125 portion and lens housing 164 integrating the second optical element 127. Optical element 125 and optical element 127 are arranged as a doublet to form first lens 112.

LED housing 162 defines a cavity in which an LED chip is disposed. The base of the cavity can be formed by a heat sink 168, such as a copper plug or other heat sink that passes through LED housing 162. A set of alignment walls 170 extending upwards from around the edges of the cavity can aid in aligning the homogenizer 120 over the LED with an air gap between the LED and entrance face 122 of homogenizer 120. According to one embodiment, the opening to cavity in which the LED is disposed and homogenizer 120 are approximately the same size.

LED housing 162 can also include alignment features to help ensure homogenizer housing structure 150 is properly aligned with LED housing 162. As one example, LED housing 162 can include bosses 172 extending from the upper surface of LED housing 162 that are received by corresponding boss receiving cavities 176 in homogenizer housing structure 150.

Homogenizer housing structure 150 comprises a portion forming optical element 125, a portion forming homogenizer 120 and a support member 174 formed of unitary piece of material or multiple parts coupled together. Optical element 125 comprises a first surface 151 facing source 105 and a second surface 152 on the opposite side of optical element 125 (an "exit surface" 152). Surface 152 is concave with geometry such that light enters optical element 127 in the acceptance angle of optical element 127. Surface 151 can be flat or have other desired shape.

Homogenizer housing structure 150 can further include a support member 174, such as an annular wall, extending from surface 151 to LED housing 162. Support member 174 can include boss receiving cavities 176 to receive bosses 172. Support member 174 creates a homogenizer cavity 177 around homogenizer 120. Typically, the cavity will be filled with air to promote TIR in homogenizer 120, though other medium may be used.

Lens housing 164, according to one embodiment, forms an integrated housing and intermediate optical element 127. Lens housing 164, in the embodiment of FIG. 7, is shaped to form a first cavity 188 (the "lens cavity") and a second cavity (the "doublet cavity") on opposite sides of optical element 127. Lens cavity 188 is defined by cavity walls 182 and a cavity base surface 184 that extends across the base of cavity 188. Cavity walls 182 extend upward from base surface 184 in a direction away from LED housing 162. The ends of cavity walls 182 are spaced so that lens 114 can rest with surface 158 of lens 114 contacting surface 156 of lens 116 or separated from surface 156 a selected distance. Thus, lens housing 164 can be used to set the focus of optical device 161. Additionally, cavity walls 182 can be spaced from the edge of optical element 127 so that all or substantially all the light projected from lens 112 can enter lens 114 without hitting the cavity walls 182.

Housing support member 186 extends from base surface 184 toward LED housing 162. According to one embodiment, housing support member 186 can comprise an annular wall that partially defines the doublet cavity. The doublet cavity is shaped to receive homogenizer housing structure 150 so that

11

concave surface **152** contacts entrance surface **154** of optical element **127** (the surface of optical element **127** facing the source).

Lens housing **164** can include features corresponding to alignment features of homogenizer housing structure **150**. For example, lens housing **164** can include alignment recesses to receive extensions **190** of homogenizer housing structure **150**. Preferably, the corresponding alignment features provide a mechanism to axially align optical element **125** with optical element **127**.

Second lens portion **155** of FIG. 7 includes lens **114** having a slightly concave surface **158** on one side and a convex surface **160** on the other side. Additionally, second lens portion **155** includes an annular flange **191** extending outward from lens **114**, perpendicular to the optical axis of second lens **114**. Flange **191** can rest on cavity wall **182** or other shoulder defined by lens housing **164**.

In FIG. 7, the inside surfaces of alignment walls **170** can be tapered so that homogenizer **120** settles in the proper position. The walls can be shaped so that homogenizer **120** is separated from the LED by a small gap.

FIGS. 8A-D are diagrammatic representations of one embodiment of homogenizer housing structure **150**. FIG. 8A is a view of homogenizer housing structure **150** looking into exit face **152** of optical element **125**, FIG. 8B is a cross-section along line B-B of FIG. 8A and FIG. 8C is a cross-section along line A-A of FIG. 8A.

According to one embodiment, homogenizer housing structure **150** comprises a generally cylindrical structure extending from a first end to a second end. Homogenizer housing structure **150** may taper outward from the first end to the second end. A surface **152** at the first end defines the exit face of optical element **125** and acts as a refractive surface to emit light in a selected beam angle. At the second end, the homogenizer housing structure **150** defines a LED frame passage **194** open at the second end of the homogenizer housing structure **150** and extending across the homogenizer housing structure **150** lateral to the optical axis of homogenizer housing structure **150**. Lateral passage **194** can be sized to accommodate the width of LED housing **162**. Homogenizer housing structure **150** further defines homogenizer cavity **177** open to lateral passage **194** and extending a distance into the homogenizer housing structure surface **151** that, in this embodiment, extends generally lateral to the optical axis of homogenizer housing structure **150**. Generally lateral surface **151** extends laterally from an annular sidewall (e.g., support member **174**) to homogenizer **120**.

Homogenizer housing structure **150** further comprises homogenizer **120** extending a length parallel to the optical axis from lateral surface **151** a distance to homogenizer entrance face **122**, defined in a plane perpendicular to the optical axis. Homogenizer **120** transitions into lens **112**, which extends from surface **151** to the exit face **152** of the optical element **125**.

The transitioning of the homogenizer **120** into lens **112** may be based on a shape of entrance face **122** of the homogenizer **120** and a shape of the virtual exit face **124** of the homogenizer **120**. For example, the entrance face **122** of the homogenizer **120** may have a square shape, whereas the exit face **124** of the homogenizer **120** may have a circular shape. Furthermore, the surface area at the exit face **124** may be equal to or greater than the surface area of the entrance face **122** of the homogenizer **120** to limit, reduce or null light loss through the homogenizer **120**. The virtual exit face **124** of homogenizer **120**, in the embodiment of FIGS. 8A-D, defines the entrance aperture **117** of first lens **112**.

12

Further, the entrance face **122** of the homogenizer **120** may be square shaped to maximize or increase the coverage of light emitted from a light source **105** and transition into an exit face **124** of a second shape such as a circle.

FIGS. 9A-B are diagrammatic representations of one embodiment of a homogenizer **120** for converting from a square to circular shape. FIG. 9A is view of homogenizer **120** looking at entrance face **122** and FIG. 9B is a diagrammatic representation of a side view of homogenizer **120**.

Homogenizer **120**, in FIGS. 9A-B, comprises entrance face **122**, exit face **124** and sidewall(s) **204** extending from entrance face **122** to exit face **124**. The shape of exit face **124** is selected to have at least the same area as entrance face **122**. In this example, the diameter of exit face **124** is approximately equal to the diagonal of entrance face **122**, making exit face **124** slightly larger than entrance face **122**. Because of the difference in shape, sidewalls **204** are slightly tapered.

The sidewalls **204** of homogenizer **120** are shaped to transition from the shape of the entrance face to the shape of the exit face (e.g., from a square entrance face **122** to a round exit face **124** or between other geometric or arbitrary shapes). The sidewalls **204** comprise multiple sets of facets, curves or other transition features. According to one embodiment a first set of facets **206** correspond to a shape of the entrance face while a second set of facets **208** correspond to a transition shape between the shape of entrance face **122** and exit face **124** (that is, a shape that begins to more closely approximate the shape of exit face **124**). Additional sets of facets can correspond to any number of other shapes between the shape of entrance face **122** and exit face **124**. In the embodiment of FIGS. 9A-B, facets **206** correspond to a square shape, and facets **208** correspond to a hexadecagon.

The shape of homogenizer **120** can be formed using a base shape having the appropriate size and shape for exit face **124**. For the example of FIGS. 9A-B, the base shape is a cylinder. Facets **206** are formed based on an extruded cut made with the shape of the entrance face **122**, with the cut tapering outward along a defined angle. Thus, facets **206** correspond to a square shape extruded cut (regardless of whether homogenizer **120** is actually formed by cutting, molding or some other process). Even more specifically, in the example of FIGS. 9A-B, facets **206** correspond to a square shape making an extruded cut with a taper angle 7.25 degrees such that the entrance face **122** has the desired shaped and size and the sidewalls taper outwards. Facets **208** are formed based on an extruded cut made using a hexadecagon with a taper angle of 1 degree.

In other embodiments, facets can correspond to other shapes with the same or different taper angles. For example, to transition from a square to a circle, facets can be formed based on extruded cuts using hexagonal, octagonal and or other shapes. The sidewalls **204** may include any number of different sets of facets formed based on any number of shapes between the shape of entrance face **122** and exit face **124**.

Furthermore, while in the embodiment of FIGS. 9A-B the transition features are formed based on straight extrusion cuts corresponding to geometric shapes, other embodiments can include transition features corresponding to arbitrary shapes. Furthermore, the transition features may include simple or complex curves to transition from the shape of entrance face **122** to exit face **124**.

In one embodiment, a homogenizer that transitions from a first shape to a second shape can be modeled in a 3-D modeling program such as SOLIDWORKS by Dassault Systems SolidWorks Corp. of Concord Mass. and the resulting shape can be entered in a ray tracing program, such as ZEMAX by

13

Radiant ZEMAX LLC of Bellevue, Wash. Ray tracing can be performed to determine the flux per unit area given by a particular shape.

Iterative adjustment of the shape of the homogenizer **120** can be performed until a satisfactory output is determined. More specifically, the number of facets, the length and/or the taper angle of the homogenizer may be iteratively adjusted. Preferably, the homogenizer is selected so that the difference in half angle of light emitted from exit face **124** and the half angle of light entering homogenizer **120** is less than 20%. Furthermore, the homogenizer is preferably configured so that the peak to valley difference of flux per unit area of light emitted is less than 10%.

With or without a homogenizer, various embodiments of optical systems can be configured so that greater than 75%, including greater than 95%, of the light entering lens **112** is projected into far field (referred to herein as transmission efficiency) in a desired beam angle (referred to as percent in beam), not counting Fresnel losses. However, even at lower transmission efficiencies and percent in beam, optical devices of the present application provide superior beam shaping capabilities. If a smaller percent in beam is desired, tradeoffs between the exit aperture and the percent in beam may also be made. Lenses can be formed to account for this tradeoff per the system requirement.

FIGS. **10-15** represents model illumination patterns of light emitted by the optical device having a lens configuration similar to that illustrated in FIG. **7** with homogenizers having different exit face shapes. As can be seen in FIGS. **10-15**, the illumination profile within the selected angle can be noticeably uniform. In these embodiments, the area of the exit face was large enough to conserve radiance and the homogenizer was configured to transition from a square entrance face shape to the exit face shape.

In FIG. **10**, both the entrance and exit faces of the homogenizer may be substantially square shaped. Of 5,000,000 rays traced, greater than 4,910,000 rays (98% of the rays) arrive on the far field detector plane, indicating near conservation of radiance in the multi-element optical stack.

In FIG. **11**, the shape of an entrance aperture may be substantially square, while the shape of the exit aperture may have a substantially square border with internal patterns to create an arbitrary shape. In FIG. **11**, of 1,000,000 rays traced, greater than 780,000 rays (78% of the rays) arrive on the far field detector plane, indicating substantial conservation of radiance in the multi-element optical stack. FIG. **11** demonstrates that light can be shaped into an arbitrary shape with high conservation of radiance (greater than 70%) in a high NA optical system.

In FIG. **12**, the shape of an entrance aperture may be substantially square, while the shape of the exit aperture may be substantially ovalar. In FIG. **12**, of 1,000,000 rays traced, greater than 994,000 rays (99% of the rays) arrive on the far field detector plane, indicating near or substantial conservation of radiance in the multi-element optical stack.

In FIG. **13**, the shape of an entrance aperture may be substantially square, while the shape of the exit aperture may be substantially rectangular. In FIG. **13**, of 1,000,000 rays traced, greater than 999,000 rays (99% of the rays) arrive on the far field detector plane, indicating near or substantial conservation of radiance in the multi-element optical stack.

In FIG. **14**, the shape of an entrance aperture may be substantially square, while the shape of the exit aperture may be substantially hexagonal. In FIG. **14**, of 1,000,000 rays traced, greater than 984,000 rays (98% of the rays) arrive on the far field detector plane, indicating near or substantial conservation of radiance in the multi-element optical stack.

14

In FIG. **15**, the shape of an entrance aperture may be substantially square, while the shape of the exit aperture may be substantially circular with a ridged circumference. In FIG. **15**, of 1,000,000 rays traced, greater than 994,000 rays (99% of the rays) arrive on the far field detector plane, indicating near or substantial conservation of radiance in the multi-element optical stack.

In the foregoing examples, the intensity distribution may not be entirely uniform due to design constraints. However, the optical system still projects an image into far field of the corresponding to the shape of the exit face **124** that is easily discernable.

FIG. **16** is a chart of radiant intensity (y-axis) versus beam angle (x-axis) and illustrates that embodiments of an optical system, such as illustrated in FIG. **4**, can act to create a “digital” light distribution in which greater than 80%, and in this case greater than 90%, of the light is within the desired beam angle and the remaining light is within a very small range to create a sharp cutoff. Using homogenizer **120** that homogenizes light from an entrance face of a first shape to an exit face of a second shape, the optical stack **110** may emit light at different patterns within a desired beam angle.

FIG. **17** illustrates the advantage of high light in beam. A high light in beam means that there is much less wasted light outside of desired projected beam angle. FIG. **17**, illustrates the difference between a system that provides 28% Lumens in Beam versus a system that provides 90% of Lumens in Beam to illustrate the advantages of embodiments described herein.

FIG. **18** illustrates one embodiment for an illumination pattern **1900** of an optical device utilizing a homogenizer (and optical device having a lens configuration similar to that illustrated in FIG. **7**) to project light onto a plane **1910**. According to one embodiment, the illumination pattern emitted by the optical device may be rhombus shape as determined by the exit face of a homogenizer. The shape of the rhombus can be selected so that when optical system projects onto plane **1910** at an angle theta θ **1920**, the illumination pattern appears square or rectangular at plane **1910**.

Thus, the optical system **1900** may utilize a homogenizer to project light at an angle theta θ **1920** towards the plane **1910** that results in a square illumination pattern. For example, the optical system **1900** may be configured to project images onto a plane **1910** that is a billboard, a wall, or any other medium capable of receiving a projected image.

FIG. **19** is a flow diagram representing one embodiment for determining the shape of a homogenizer **120** as referenced above.

In **S2000**, the shape of an entrance face of a homogenizer may be determined. The entrance face may be based on any criteria or user preference. Further, the shape of the entrance face may be determined so that all or substantially of the light emitted by a source enters the entrance face. Therefore, the shape of the entrance face may be based on the dimensions and shape of a light source.

In **S2010**, the shape of an exit face of the homogenizer may be determined. The shape of the exit face may be any shape. Further, the shape of the exit face may be determined to reduce the beam angle of the light emitted by the homogenizer. Further, the exit face may be configured to conserve the amount of light emitted at the exit face.

In **S2020**, the length of the homogenizer may be determined. The length of the homogenizer may be determined to fit within an LED housing or any other design requirements of an optical system. Further, the length of the homogenizer may be based on the design criteria for flux per unit area of the exit face. As such, longer homogenizers allow light to bounce a plurality of times off the sidewalls of the homogenizers as

15

light propagates through the homogenizer. Therefore, longer homogenizers allow for greater angular control of the light within the homogenizer and may emit substantially uniform light at the exit face of the homogenizer.

In S2030, the taper angle of the sidewalls of the homogenizer may be determined. However, in particular embodiments the sidewalls of the homogenizer may not be tapered. Further, the taper angle/angles of the sidewalls may be angled to transition from the first shape of the entrance face to the second shape of the exit face.

In S2040, the configuration of the transition features can be determined. For example, the number of facets, curves or other transition features in the homogenizer and the shapes of the facets, curves or other transition features, the regularity of the facets, curves or other transition features or other aspects may be determined. The number/shapes of transitions features in the homogenizer may be based on the shape of the entrance face and/or the exit face. For example, a number of facets may be based on a number of edges of the exit face, such as the number of facets may be a multiple of the number of edges of the exit face.

In S2050, it is determined if the light emitted from the exit face is within design criteria for the optical system. For example, it may be desired that the difference in the half angle of the light emitted from the exit face and the half angle of the light entering the homogenizer at the entrance face is less than 2%, and the peak to valley difference of flux per unit area of light emitted is less than 5% at the homogenizer exit face. Other design criteria may include the percent light in beam or percent conservation of radiance of an overall optical system incorporating the homogenizer.

In S2060, if the light emitted from the exit face of the homogenizer does not meet desired or required criteria, S2020, S2030, and/or S2040 may be iteratively modified. For example, the length of the homogenizer may be increased, the taper angle of the homogenizer may be increased and/or the number/shapes of transition features in the homogenizer may be changed.

FIG. 20 is a diagrammatic representation of one embodiment of an optical system similar to that illustrated in FIG. 3, but indicating that homogenizer 120 can have a shaped section 211. According to one embodiment, shaped section 211 can have sidewalls shaped as described in U.S. Pat. No. 7,772,604 to prevent losses at the sidewalls. FIG. 21 is a diagrammatic representation of another embodiment of an optical system similar to that illustrated in FIG. 3, illustrating that the homogenizer 120 can have tapered sidewalls.

Those skilled in the arts will appreciate after reading this disclosure that dimensions and other data provided herein are exemplary and that embodiments disclosed herein may be manufactured according to other dimensions or data without limiting the scope of the disclosure.

Although embodiments have been described in detail herein, it should be understood that the description is by way of example only and is not to be construed in a limiting sense. It is to be further understood, therefore, that numerous changes in the details of the embodiments and additional embodiments will be apparent, and may be made by, persons of ordinary skill in the art having reference to this description. It is contemplated that all such changes and additional embodiments are within scope of the disclosure and its legal equivalents.

What is claimed is:

1. An optical system comprising:

a homogenizer configured to emit light that has a half angle that is at least 80% of a half angle of light entering the homogenizer, the homogenizer comprising:

16

an entrance face positioned to receive light from a source, the entrance face having a first shape;

a body configured to homogenize light received through the entrance face by reflecting the light a plurality of times off sidewalls of the body; and

an exit face configured to emit light, the exit face parallel to the entrance face; and

an imaging high numerical aperture optical system coupled to the exit face of the homogenizer.

2. The system of claim 1, wherein the entrance face and exit face have approximately a same area.

3. The system of claim 1, wherein the exit face has an area at least equal to

$$\frac{n^2 A \Omega}{n'^2 \Omega'}$$

wherein Ω is an effective solid angle in which light enters the homogenizer, Ω' is the effective solid angle whereby light leaves the homogenizer, A is the area of the entrance face, n is a refractive index of a medium from which light is received by the homogenizer, n' is a refractive index of material into which the homogenizer emits.

4. The system of claim 1, wherein the exit face has an area at least equal to

$$\frac{n^2 A \pi}{n'^2 \Omega'}$$

wherein Ω' is an effective solid angle whereby light leaves the homogenizer, A is the area of the entrance face, n is a refractive index of a medium from which light is received by the homogenizer, n' is a refractive index of a material into which the homogenizer emits.

5. The system of claim 1, wherein the body is tapered outward from the entrance face.

6. The system of claim 5, wherein the exit face has a second shape different than the first shape and the homogenizer comprises a set of transition features transitioning from the first shape to the second shape.

7. The system of claim 6, wherein the transition features comprise a set of sidewall facets transitioning to the second shape.

8. The system of claim 7, wherein the second shape has a surface area greater than or equal to a surface area of the first shape.

9. The system of claim 7, wherein the set of sidewall facets comprises a first set of facets corresponding to an extruded cut of the first shape, the cut tapering outward according to a first taper angle.

10. The system of claim 9, wherein the set of sidewall facets comprise a second set of facets corresponding to an extruded cut of a third shape tapering outward according to a second taper angle.

11. The system of claim 1, wherein the homogenizer is formed of at least one of plastic, PMMA, glass and silicone.

12. The system of claim 1, wherein the high numerical aperture optical system comprises an imaging multi-element optical stack comprising a series of lenses optically coupled to the exit face of the homogenizer, wherein a first lens of the series of lenses is directly coupled to the exit face of the homogenizer, the lenses in the series of lenses configured, in combination, to successively reduce a beam angle of light from a first beam angle to an emission beam angle and emit in

17

an emission beam angle at least 70% of the light entering the series of lenses from the homogenizer.

13. The system of claim 1, wherein the imaging high numerical aperture optical system comprises an optical device configured to emit at least 70% of the light entering the optical device from the homogenizer in a controlled beam angle.

14. The system of claim 1, further comprising an encapsulant contacting the entrance face and wherein the imaging high numerical aperture system comprises a lens having a same index of refraction as the encapsulant.

15. The system of claim 1, wherein the exit face is a virtual exit face.

16. The system of claim 1, wherein the exit face is physical exit face.

17. A method of homogenizing light, comprising:
receiving light at an entrance face of a homogenizer, the entrance face having a first shape;

homogenizing light received through the entrance face by reflecting the light a plurality of times in the homogenizer; and

emitting homogenized light from an exit face of the homogenizer that is parallel to the entrance face of the homogenizer, the light emitted with a half angle that is at least 80% of the half angle of light entering the homogenizer into an imaging high numerical aperture system coupled to the exit face of the homogenizer.

18

18. The method of claim 17, wherein light is emitted from the exit face in a second shape different than the first shape.

19. The method of claim 17, wherein the high numerical aperture imaging system comprises a series of lenses that are configured, in combination, to successively reduce a beam angle of light from a first beam angle to an emission beam angle and emit in an emission beam angle at least 70% of the light entering the series of lenses from the homogenizer.

20. The method of claim 17, wherein the high numerical aperture imaging system is configured to emit in a controlled beam angle at least 70% of the light received from the homogenizer.

21. The method of claim 17, wherein:

the exit face has a second shape; and

the homogenizer further comprises:

a first set of sidewall facets corresponding to the first shape tapered outward at a first taper angle relative to an axis running from the entrance face to the exit face; and

a second set of sidewall facets corresponding to a third shape, the second set of facets tapered outward at a second taper angle relative to the axis.

22. The method of claim 21, wherein the entrance face is square and the exit face is circular.
